

## Domain Resend

If a packet is followed by a return from the system board of this type, the data or subpacket checksum in the packet that generated this packet was incorrect. This type of message should cause the host machine to resend.

### TEMPORARY NOTE

Currently the domain responds to all errors with this packet type. This will be fixed in the future. So, # of resends should be limited to a reasonable number or malformed packet specifications in your program could cause an infinite loop.
